Map and Crowd Data

Understand the live map layers, sensor information and six-hour pedestrian forecast.

Built for quieter decisions

QuietMel combines pedestrian activity, place search and walking routes in one map-first experience.

Live crowd view

1

Heatmap

Colour intensity summarises the latest available pedestrian counts. Higher intensity indicates busier areas.

2

Sensors

Markers show stored sensor locations. Select a marker to inspect its place name, count and available location details.

3

Combined

The heatmap stays beneath sensor markers and detail panels so both context and individual readings remain visible.

Refresh and data timing

1

Automatic updates

QuietMel periodically requests a recent pedestrian snapshot while the map is active.

2

Manual refresh

The refresh control asks the backend for a fresh copy instead of relying on the current browser result.

3

Latest available data

Sensor feeds can report with a short delay. Treat the map as a recent activity guide, not an exact headcount at your position.

Forecast mode

1

Six-hour horizon

Forecast begins from the current time and presents expected pedestrian activity for the next six hours.

2

How to read it

Use play, pause and the time controls to compare how activity may change across the map.

3

Zero values

A value of zero means the model expects no pedestrians for that sensor and time period. It is not treated as missing data.

Data sources

Live observations come from the City of Melbourne pedestrian sensor feed. Forecast profiles are read from QuietMel's database and are based on two years of rolling historical data.
